Lecture 5: Geproci sets

Introduction

Today everything will be over the complex numbers, \mathbb{C} .

We begin with a special case of Bézout's theorem.

Today everything will be over the complex numbers, \mathbb{C} .

We begin with a special case of Bézout's theorem.

Theorem. (Bézout) *Let C_1 and C_2 be plane curves defined by squarefree homogeneous polynomials f_1 and f_2 , with no common component.*

Assume $\deg(f_1) = a$ and $\deg(f_2) = b$.

Then C_1 and C_2 meet in at most ab points: $|C_1 \cap C_2| \leq ab$.

Furthermore ...

- ▶ *If C_1 meets C_2 transversally at every intersection point then $|C_1 \cap C_2| = ab$.*

- ▶ *If C_1 meets C_2 transversally at every intersection point then $|C_1 \cap C_2| = ab$.*
- ▶ *In any case they meet in a **zero-dimensional scheme** of degree exactly ab .*

- ▶ If C_1 meets C_2 transversally at every intersection point then $|C_1 \cap C_2| = ab$.
- ▶ In any case they meet in a *zero-dimensional scheme* of degree exactly ab .

“Most of the time” a curve of degree a will meet a curve of degree b in ab distinct points.

“Most of the time” a curve of degree a will meet a curve of degree b in ab distinct points.

Definition. A set Z of ab distinct points in \mathbb{P}^2 is a **complete intersection of type (a, b)** if there exist a curve C_1 of degree a and a curve C_2 of degree b such that $Z = C_1 \cap C_2$.

We've mentioned complete intersections a few times this week.

“Most of the time” a curve of degree a will meet a curve of degree b in ab distinct points.

Definition. A set Z of ab distinct points in \mathbb{P}^2 is a **complete intersection of type (a, b)** if there exist a curve C_1 of degree a and a curve C_2 of degree b such that $Z = C_1 \cap C_2$.

We've mentioned complete intersections a few times this week.

Today we'll look at a recently born area closely related to complete intersections.

We also need the notion of a **projection** π_P .

We also need the notion of a **projection** π_P .

Let H be a plane in \mathbb{P}^3 and let P be a point not in H .

P

For us P will usually be a general point.

We also need the notion of a **projection** π_P .

Let H be a plane in \mathbb{P}^3 and let P be a point not in H .

Let $Q_1 \in \mathbb{P}^3$, $Q_1 \neq P$.

We also need the notion of a **projection** π_P .

Let H be a plane in \mathbb{P}^3 and let P be a point not in H .

Let λ_{Q_1} be the line spanned by P and Q_1 .

We also need the notion of a **projection** π_P .

Let H be a plane in \mathbb{P}^3 and let P be a point not in H .

Define $\pi_P(Q_1)$ to be $H \cap \lambda_{Q_1}$.

We also need the notion of a **projection** π_P .

Let H be a plane in \mathbb{P}^3 and let P be a point not in H .

We also need the notion of a **projection** π_P .

Let H be a plane in \mathbb{P}^3 and let P be a point not in H .

We also need the notion of a **projection** π_P .

Let H be a plane in \mathbb{P}^3 and let P be a point not in H .

We also need the notion of a **projection** π_P .

Let H be a plane in \mathbb{P}^3 and let P be a point not in H .

We get the **projection** $\pi_P : \mathbb{P}^3 \setminus \{P\} \rightarrow H = \mathbb{P}^2$.

Ancient History

Ancient History

(For us, “ancient history” means 2011.)

(For us, “ancient history” means 2011.)

Question. (Francesco Polizzi, MathOverflow, June 8, 2011)

Let $d \geq 3$ be a positive integer and let $Z \subset \mathbb{P}^3$ be a subset made of d^2 distinct points, with the following property:

*for a **general** projection $\pi : \mathbb{P}^3 \rightarrow \mathbb{P}^2$, the subset $\pi(Z) \subset \mathbb{P}^2$ is the complete intersection of two plane curves of degree d .*

(For us, “ancient history” means 2011.)

Question. (Francesco Polizzi, MathOverflow, June 8, 2011)

Let $d \geq 3$ be a positive integer and let $Z \subset \mathbb{P}^3$ be a subset made of d^2 distinct points, with the following property:

*for a **general** projection $\pi : \mathbb{P}^3 \rightarrow \mathbb{P}^2$, the subset $\pi(Z) \subset \mathbb{P}^2$ is the complete intersection of two plane curves of degree d .*

Is it true that Z itself is contained in a plane (and is the complete intersection of two curves of degree d)?

If not, what is a counterexample?

Comments:

1. It's clear (as noted by Polizzi) that if Z is itself already a complete intersection in some plane then $\pi_P(Z)$ is a complete intersection in H . We'll call these **trivial** examples.

Comments:

1. It's clear (as noted by Polizzi) that if Z is itself already a complete intersection in some plane then $\pi_P(Z)$ is a complete intersection in H . We'll call these **trivial** examples.
2. A non-degenerate set of 4 points is also an obvious example.

Comments:

1. It's clear (as noted by Polizzi) that if Z is itself already a complete intersection in some plane then $\pi_P(Z)$ is a complete intersection in H . We'll call these **trivial** examples.
2. A non-degenerate set of 4 points is also an obvious example.
3. There is no reason to restrict to d^2 points. Better: does there exist a set Z of ab points in \mathbb{P}^3 whose general projection is a complete intersection of type (a, b) ?
Without loss of generality assume $a \leq b$.

Comments:

1. It's clear (as noted by Polizzi) that if Z is itself already a complete intersection in some plane then $\pi_P(Z)$ is a complete intersection in H . We'll call these **trivial** examples.
2. A non-degenerate set of 4 points is also an obvious example.
3. There is no reason to restrict to d^2 points. Better: does there exist a set Z of ab points in \mathbb{P}^3 whose general projection is a complete intersection of type (a, b) ?
Without loss of generality assume $a \leq b$.

4. Trivial if $a = 1$. So assume $2 \leq a \leq b$.

5. We'll call such a set Z a **geproci** set because its **General Projection** is a **Complete Intersection**.

5. We'll call such a set Z a **geproci** set because its **General Projection** is a **Complete Intersection**.
6. For any values of a, b there is a large class of slightly less obvious geproci sets Z , as noticed almost immediately in 2011 by Dmitri Panov and posted on MathOverflow:

On any smooth quadric surface Q in \mathbb{P}^3 , take a lines, L_1, \dots, L_a , from one ruling and b lines, M_1, \dots, M_b from the other.

(Image from Wikipedia)

We have $|L_i \cap L_j| = 0$ and $|L_i \cap M_j| = 1$ for all i, j .

We have $|L_i \cap L_j| = 0$ and $|L_i \cap M_j| = 1$ for all i, j .

Let Z be the following intersection on Q :

$$(L_1 \cup \cdots \cup L_a) \cap (M_1 \cup \cdots \cup M_b).$$

Then $|Z| = ab$.

We have $|L_i \cap L_j| = 0$ and $|L_i \cap M_j| = 1$ for all i, j .

Let Z be the following intersection on Q :

$$(L_1 \cup \cdots \cup L_a) \cap (M_1 \cup \cdots \cup M_b).$$

Then $|Z| = ab$.

The projection $\pi(Z)$ from a general point in \mathbb{P}^3 is the complete intersection of the union of a projected lines with a union of b projected lines. So such a set is a nontrivial geproci set.

We call such a set Z a **grid**.

New Version of our Question.

- ▶ *Do there exist nontrivial, non-grid geproci sets?*

(For the rest of this question, “geproci” assumes nontrivial and non-grid.)

New Version of our Question.

We had no idea that Polizzi's question even existed!

At the 2018 conference

“Lefschetz Properties and Jordan Type in Algebra, Geometry and Combinatorics”

in Levico Terme, Italy, one workgroup working on something apparently unrelated stumbled on the first known non-trivial, non-grid example of a geproci set.

We had no idea that Polizzi's question even existed!

This was followed by a paper by Luca Chiantini and JM (TAMS 2021), which included an appendix written by all participants of the workgroup.

The main part of the paper introduced the problem, pointed out the grid example, and made connections to [unexpected hypersurfaces](#). The term “geproci” was not yet introduced.

The main part of the paper introduced the problem, pointed out the grid example, and made connections to [unexpected hypersurfaces](#). The term “geproci” was not yet introduced.

The main result was that any $(3, 3)$ -geproci set has to be a grid.

The main part of the paper introduced the problem, pointed out the grid example, and made connections to [unexpected hypersurfaces](#). The term “geproci” was not yet introduced.

The main result was that any $(3, 3)$ -geproci set has to be a grid.

The appendix gave all then-known geproci examples that arise in the same way that the original Levico observation arose.

The main result was that any $(3, 3)$ -geproci set has to be a grid.

The appendix gave all then-known geproci examples that arise in the same way that the original Leveco observation arose.

When the paper was uploaded to the arXiv, Polizzi pointed out to us his MathOverflow posting and the fact that grids were already known to have the general projection property.

The paper was modified to credit him with the question and to credit Panov with the grid observation.

Shortly afterwards, a group in Poland put out some papers introducing the term “geproci” and making further studies of the examples coming from the Levico work.

Two of the Polish group were in the Levico workgroup.

Shortly afterwards, a group in Poland put out some papers introducing the term “geproci” and making further studies of the examples coming from the Levico work.

Two of the Polish group were in the Levico workgroup.

Work continued very quickly and energetically, and we merged into a long-term project involving three of the Polish group, two Italians and two Americans.

Shortly afterwards, a group in Poland put out some papers introducing the term “geproci” and making further studies of the examples coming from the Levico work.

Two of the Polish group were in the Levico workgroup.

Work continued very quickly and energetically, and we merged into a long-term project involving three of the Polish group, two Italians and two Americans.

This group has now been working together extensively for about 2.5 years on the main questions mentioned above, and many related questions.

This is the POLITUS group.

(This is why doing math is so much fun!!)

(This is why doing math is so much fun!!)

Today we'll talk about some of the results of this work.

All results mentioned from now on are from the POLITUS group.

The D_4 configuration

The smallest nontrivial, non-grid example of a geproci set is called the D_4 configuration.

It is a set of 12 points, not on a quadric surface (hence non-grid,) which nevertheless has a lot of collinearities.

The D_4 configuration

The smallest nontrivial, non-grid example of a geproci set is called the D_4 configuration.

It is a set of 12 points, not on a quadric surface (hence non-grid,) which nevertheless has a lot of collinearities.

Theorem. Any nontrivial, non-grid geproci set of 12 points is projectively equivalent to D_4 .

The D_4 configuration

The smallest nontrivial, non-grid example of a geproci set is called the D_4 configuration.

It is a set of 12 points, not on a quadric surface (hence non-grid,) which nevertheless has a lot of collinearities.

Theorem. Any nontrivial, non-grid geproci set of 12 points is *projectively equivalent* to D_4 .

Furthermore, its structure is representative of most known geproci sets.

What does D_4 look like?

The D_4 configuration is the union of a $(3, 3)$ -grid, which lies on a unique quadric, and an additional set of three collinear points **not** on that quadric.

What does D_4 look like?

The D_4 configuration is the union of a $(3, 3)$ -grid, which lies on a unique quadric, and an additional set of three collinear points **not** on that quadric.

Hence D_4 is not a grid.

What does D_4 look like?

The D_4 configuration is the union of a $(3, 3)$ -grid, which lies on a unique quadric, and an additional set of three collinear points **not** on that quadric.

Hence D_4 is not a grid.

There are several different ways to decompose D_4 as such a union!

Up to projective equivalence, the D_4 configuration consists of the points

$$[0, 0, 1, 0], [0, 1, 1, 1], [0, 1, 0, 1]$$

$$[1, 0, 1, 1], [0, 0, 1, 1], [1, 0, 0, 0]$$

$$[1, 0, 0, 1], [0, 1, 0, 0], [1, 1, 0, 1]$$

$$[0, 0, 0, 1], \left[\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, 1\right], [1, 1, 1, 1]$$

Up to projective equivalence, the D_4 configuration consists of the points

$$\begin{aligned} & [0, 0, 1, 0], [0, 1, 1, 1], [0, 1, 0, 1] \\ & [1, 0, 1, 1], [0, 0, 1, 1], [1, 0, 0, 0] \\ & [1, 0, 0, 1], [0, 1, 0, 0], [1, 1, 0, 1] \\ & [0, 0, 0, 1], \left[\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, 1\right], [1, 1, 1, 1] \end{aligned}$$

The top 9 points are a (3,3)-grid on a unique quadric \mathcal{Q} .

The last row is not on \mathcal{Q} .

Up to projective equivalence, the D_4 configuration consists of the points

$$\begin{aligned} & [0, 0, 1, 0], [0, 1, 1, 1], [0, 1, 0, 1] \\ & [1, 0, 1, 1], [0, 0, 1, 1], [1, 0, 0, 0] \\ & [1, 0, 0, 1], [0, 1, 0, 0], [1, 1, 0, 1] \\ & [0, 0, 0, 1], \left[\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, 1\right], [1, 1, 1, 1] \end{aligned}$$

The top 9 points are a (3,3)-grid on a unique quadric \mathcal{Q} .

The last row is not on \mathcal{Q} .

Note: There are no four collinear points.

Up to projective equivalence, the D_4 configuration consists of the points

$$\begin{aligned} & [0, 0, 1, 0], [0, 1, 1, 1], [0, 1, 0, 1] \\ & [1, 0, 1, 1], [0, 0, 1, 1], [1, 0, 0, 0] \\ & [1, 0, 0, 1], [0, 1, 0, 0], [1, 1, 0, 1] \\ & [0, 0, 0, 1], \left[\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, 1\right], [1, 1, 1, 1] \end{aligned}$$

The top 9 points are a (3,3)-grid on a unique quadric \mathcal{Q} .

The last row is not on \mathcal{Q} .

Note: There are no four collinear points.

Here's one way to visualize it:

(Not visible: the back vertex point $[1, 1, 1, 1]$, the center point $[\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, 1]$ and the orthogonal lines through the point $[1, 1, 1, 1]$ along the three back edges.)

Some Main Results

Theorem. (Classification of $(3, b)$ -geproci sets)

Let Z be a $(3, b)$ -geproci set Z .

Then Z is necessarily a $(3, b)$ -grid (on a quadric surface), except for the case $b = 4$, where Z can also be the D_4 configuration (up to projective equivalence).

Some Main Results

Theorem. (Classification of $(3, b)$ -geproci sets)

Let Z be a $(3, b)$ -geproci set Z .

Then Z is necessarily a $(3, b)$ -grid (on a quadric surface), except for the case $b = 4$, where Z can also be the D_4 configuration (up to projective equivalence).

Lemma. (Liaison trick)

Let Z be (a, b) -geproci and assume that Z contains a set of a collinear points. Then the removal of these points is an $(a, b - 1)$ -geproci set.

This also holds if we allow $a > b$.

Example. Recall the D_4 configuration, which is $(3, 4)$ -geproci:

$$[0, 0, 1, 0], [0, 1, 1, 1], [0, 1, 0, 1]$$

$$[1, 0, 1, 1], [0, 0, 1, 1], [1, 0, 0, 0]$$

$$[1, 0, 0, 1], [0, 1, 0, 0], [1, 1, 0, 1]$$

$$[0, 0, 0, 1], \left[\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, 1\right], [1, 1, 1, 1]$$

Example. Recall the D_4 configuration, which is $(3, 4)$ -geproci:

$$[0, 0, 1, 0], [0, 1, 1, 1], [0, 1, 0, 1]$$

$$[1, 0, 1, 1], [0, 0, 1, 1], [1, 0, 0, 0]$$

$$[1, 0, 0, 1], [0, 1, 0, 0], [1, 1, 0, 1]$$

$$[0, 0, 0, 1], \left[\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, 1\right], [1, 1, 1, 1]$$

Obviously removing the last row leaves a $(3, 3)$ -grid, which is geproci.

Example. Recall the D_4 configuration, which is $(3, 4)$ -geproci:

$$\begin{aligned} & [0, 0, 1, 0], [0, 1, 1, 1], [0, 1, 0, 1] \\ & [1, 0, 1, 1], [0, 0, 1, 1], [1, 0, 0, 0] \\ & [1, 0, 0, 1], [0, 1, 0, 0], [1, 1, 0, 1] \\ & [0, 0, 0, 1], [\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, 1], [1, 1, 1, 1] \end{aligned}$$

Obviously removing the last row leaves a $(3, 3)$ -grid, which is geproci.

But also removing any other row leaves a $(3, 3)$ -geproci set by the Lemma.

Example. Recall the D_4 configuration, which is $(3, 4)$ -geproci:

$$\begin{aligned} & [0, 0, 1, 0], [0, 1, 1, 1], [0, 1, 0, 1] \\ & [1, 0, 1, 1], [0, 0, 1, 1], [1, 0, 0, 0] \\ & [1, 0, 0, 1], [0, 1, 0, 0], [1, 1, 0, 1] \\ & [0, 0, 0, 1], \left[\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, 1\right], [1, 1, 1, 1] \end{aligned}$$

Obviously removing the last row leaves a $(3, 3)$ -grid, which is geproci.

But also removing any other row leaves a $(3, 3)$ -geproci set by the Lemma. This set is also a grid by the CM result.

Theorem. (The Standard Construction)

Fix any integer $a \geq 3$.

Let u be a primitive a -th root of unity.

Theorem. (The Standard Construction)

Let u be a primitive a -th root of unity.

Let Q be the quadric surface in \mathbb{P}^3 defined by $xw - yz = 0$.

Theorem. (The Standard Construction)

Fix any integer $a \geq 3$.

Let u be a primitive a -th root of unity.

Let \mathcal{Q} be the quadric surface in \mathbb{P}^3 defined by $xw - yz = 0$.

Let X be the following a^2 points; X forms a grid on \mathcal{Q} .

$$\begin{array}{ccccccc} [1, 1, 1, 1], & [1, u, 1, u], & [1, u^2, 1, u^2], & \dots & [1, u^{a-1}, 1, u^{a-1}] \\ [1, 1, u, u], & [1, u, u, u^2], & [1, u^2, u, u^3], & \dots & [1, u^{a-1}, u, 1] \\ [1, 1, u^2, u^2], & [1, u, u^2, u^3], & [1, u^2, u^2, u^4], & \dots & [1, u^{a-1}, u^2, u] \\ \vdots & \vdots & \vdots & & \vdots \\ [1, 1, u^{a-1}, u^{a-1}], & [1, u, u^{a-1}, 1], & [1, u^2, u^{a-1}, u], & \dots & [1, u^{a-1}, u^{a-1}, u^{a-2}] \end{array}$$

Let

▶ $Y_1 = \{[1, 0, 0, -1], [1, 0, 0, -u], \dots, [1, 0, 0, -u^{a-1}]\}$

▶ $Y_2 = \{[0, 1, -1, 0], [0, 1, -u, 0], \dots, [0, 1, -u^{a-1}, 0]\}$.

Let

▶ $Y_1 = \{[1, 0, 0, -1], [1, 0, 0, -u], \dots, [1, 0, 0, -u^{a-1}]\}$

▶ $Y_2 = \{[0, 1, -1, 0], [0, 1, -u, 0], \dots, [0, 1, -u^{a-1}, 0]\}$.

The points Y_1 are collinear, the points Y_2 are collinear, and all lie off Q .

Let

▶ $Y_1 = \{[1, 0, 0, -1], [1, 0, 0, -u], \dots, [1, 0, 0, -u^{a-1}]\}$

▶ $Y_2 = \{[0, 1, -1, 0], [0, 1, -u, 0], \dots, [0, 1, -u^{a-1}, 0]\}$.

The points Y_1 are collinear, the points Y_2 are collinear, and all lie *off* \mathcal{Q} . Then

(a) Both $X \cup Y_1$ and $X \cup Y_2$ are $(a, a + 1)$ -geproci.

Let

$$\blacktriangleright Y_1 = \{[1, 0, 0, -1], [1, 0, 0, -u], \dots, [1, 0, 0, -u^{a-1}]\}$$

$$\blacktriangleright Y_2 = \{[0, 1, -1, 0], [0, 1, -u, 0], \dots, [0, 1, -u^{a-1}, 0]\}.$$

The points Y_1 are collinear, the points Y_2 are collinear, and all lie *off* \mathcal{Q} . Then

(a) Both $X \cup Y_1$ and $X \cup Y_2$ are $(a, a + 1)$ -geproci.

(b) If a is even then in addition, $X \cup Y_1 \cup Y_2$ is $(a, a + 2)$ -geproci.

Let

- ▶ $Y_1 = \{[1, 0, 0, -1], [1, 0, 0, -u], \dots, [1, 0, 0, -u^{a-1}]\}$
- ▶ $Y_2 = \{[0, 1, -1, 0], [0, 1, -u, 0], \dots, [0, 1, -u^{a-1}, 0]\}$.

The points Y_1 are collinear, the points Y_2 are collinear, and all lie *off* Q . Then

- (a) Both $X \cup Y_1$ and $X \cup Y_2$ are $(a, a + 1)$ -geproci.
- (b) If a is even then in addition, $X \cup Y_1 \cup Y_2$ is $(a, a + 2)$ -geproci.

Since these geproci sets do not lie on a quadric, they are not grids.

Note the similarity with D_4 ((3, 3)-grid plus 3 collinear points). In fact D_4 comes from the standard construction ($a = 3$) (up to projective equivalence).

Note the similarity with D_4 ((3, 3)-grid plus 3 collinear points). In fact D_4 comes from the standard construction ($a = 3$) (up to projective equivalence).

Corollary. (Numerical classification of geproci sets)

Note the similarity with D_4 ((3, 3)-grid plus 3 collinear points). In fact D_4 comes from the standard construction ($a = 3$) (up to projective equivalence).

Corollary. (Numerical classification of geproci sets)

Fix integers a, b with $1 \leq a \leq b$.

Note the similarity with D_4 ((3, 3)-grid plus 3 collinear points). In fact D_4 comes from the standard construction ($a = 3$) (up to projective equivalence).

Corollary. (Numerical classification of geproci sets)

Fix integers a, b with $1 \leq a \leq b$.

- ▶ *If $a = 1$ or $a = 2$ then there are no non-trivial, non-grid geproci sets.*

Note the similarity with D_4 ($(3, 3)$ -grid plus 3 collinear points). In fact D_4 comes from the standard construction ($a = 3$) (up to projective equivalence).

Corollary. (Numerical classification of geproci sets)

Fix integers a, b with $1 \leq a \leq b$.

- ▶ If $a = 1$ or $a = 2$ then there are no non-trivial, non-grid geproci sets.
- ▶ If $a = 3$ then the only non-trivial, non-grid geproci set is D_4 (up to projective equivalence), which is $(3, 4)$ -geproci.

Note the similarity with D_4 ($(3, 3)$ -grid plus 3 collinear points). In fact D_4 comes from the standard construction ($a = 3$) (up to projective equivalence).

Corollary. (Numerical classification of geproci sets)

Fix integers a, b with $1 \leq a \leq b$.

- ▶ If $a = 1$ or $a = 2$ then there are no non-trivial, non-grid geproci sets.
- ▶ If $a = 3$ then the only non-trivial, non-grid geproci set is D_4 (up to projective equivalence), which is $(3, 4)$ -geproci.
- ▶ If $4 \leq a \leq b$ then there is a non-trivial, non-grid (a, b) -geproci set.

Note the similarity with D_4 ((3, 3)-grid plus 3 collinear points). In fact D_4 comes from the standard construction ($a = 3$) (up to projective equivalence).

Corollary. (Numerical classification of geproci sets)

Fix integers a, b with $1 \leq a \leq b$.

- ▶ If $a = 1$ or $a = 2$ then there are no non-trivial, non-grid geproci sets.
- ▶ If $a = 3$ then the only non-trivial, non-grid geproci set is D_4 (up to projective equivalence), which is (3, 4)-geproci.
- ▶ If $4 \leq a \leq b$ then there is a non-trivial, non-grid (a, b) -geproci set.

Idea of proof:

It is a consequence of the liaison trick. (Example coming.)

Example. How would we construct a $(4, 8)$ -geproci set?

Example. How would we construct a $(4, 8)$ -geproci set?

Step 1: Use the standard construction to construct an $(8, 9)$ -geproci set.

This consists of an $(8, 8)$ -grid, X , on a quadric \mathcal{Q} plus a set Y_1 of 8 collinear points not on \mathcal{Q} .

Example. How would we construct a $(4, 8)$ -geproci set?

Step 1: Use the standard construction to construct an $(8, 9)$ -geproci set.

This consists of an $(8, 8)$ -grid, X , on a quadric \mathcal{Q} plus a set Y_1 of 8 collinear points not on \mathcal{Q} .

Step 2: Use the liaison trick to remove a set of 8 collinear points **from X** , giving an $(8, 9 - 8) = (8, 8)$ -geproci set.

Step 3: Take four more sets of 8 collinear points from the same ruling of the grid, to get the $(8, 8 - 4) = (8, 4) = (4, 8)$ -geproci set.

Step 3: Take four more sets of 8 collinear points from the same ruling of the grid, to get the $(8, 8 - 4) = (8, 4) = (4, 8)$ -geproci set.

Step 4: Observe that since we are removing sets of 8 points always from X , what's left is:

Step 3: Take four more sets of 8 collinear points from the same ruling of the grid, to get the $(8, 8 - 4) = (8, 4) = (4, 8)$ -geproci set.

Step 4: Observe that since we are removing sets of 8 points always from X , what's left is:

- ▶ 3 sets of 8 collinear points on \mathcal{Q} (a $(3, 8)$ -grid)

Step 3: Take four more sets of 8 collinear points from the same ruling of the grid, to get the $(8, 8 - 4) = (8, 4) = (4, 8)$ -geproci set.

Step 4: Observe that since we are removing sets of 8 points always from X , what's left is:

- ▶ 3 sets of 8 collinear points on \mathcal{Q} (a $(3, 8)$ -grid)
- ▶ the set Y_1 not on \mathcal{Q} .

Step 3: Take four more sets of 8 collinear points from the same ruling of the grid, to get the $(8, 8 - 4) = (8, 4) = (4, 8)$ -geproci set.

Step 4: Observe that since we are removing sets of 8 points always from X , what's left is:

- ▶ 3 sets of 8 collinear points on \mathcal{Q} (a $(3, 8)$ -grid)
- ▶ the set Y_1 not on \mathcal{Q} .

Thus we have a $(4, 8)$ non-grid geproci set.

Final Remarks.

1. All the examples so far have been **half-grids**.

Final Remarks.

1. All the examples so far have been **half-grids**.

That is, we have non-grid (a, b) -geproci sets consisting of (very specially chosen) sets of points on lines:

- ▶ b lines with a collinear points each, or
- ▶ a lines with b collinear points each.

Final Remarks.

1. All the examples so far have been **half-grids**.

That is, we have non-grid (a, b) -geproci sets consisting of (very specially chosen) sets of points on lines:

- ▶ b lines with a collinear points each, or
- ▶ a lines with b collinear points each.

But in fact there exist nontrivial, non-grid geproci sets that are not half-grids.

But only a very small number are known, and they have large subsets that are half-grids.

2. We are near classification of half-grid $(4, b)$ -geproci sets.

2. We are near classification of half-grid $(4, b)$ -geproci sets.
3. An extension of the standard construction gives **infinite families** of non-projectively equivalent, nontrivial, half-grid geproci sets for all choices of $4 \leq a \leq b$.

2. We are near classification of half-grid $(4, b)$ -geproci sets.
3. An extension of the standard construction gives **infinite families** of non-projectively equivalent, nontrivial, half-grid geproci sets for all choices of $4 \leq a \leq b$.

So geproci sets are hard to come by, but there are a lot more of them than you might think!!!

4. There are still many things we do not know about them.

E.g. we conjecture that non-trivial geproci sets in \mathbb{P}^3 cannot be in linear general position (i.e. no four on a plane).
