Abstract

This paper examines the effectiveness of leaders in addressing coordination failure in societies with ethnic or religious diversity. We experimentally vary leader identity in a coordination game and implement it in the field across 44 towns in India. We find that religious minority leaders (Muslims) improve coordination, while majority leaders (Hindus) do not. We test the effectiveness of intergroup contact and affirmative action, two commonly used policies to improve the well-being of minorities. Intergroup contact improves coordination irrespective of leader identity, but affirmative action leads to deterioration in coordination in Muslim-led groups alongside an increase in coordination in Hindu-led groups. We find that both policies are less effective for Muslim-led groups in towns with a recent history of religious conflict. Our findings contribute novel evidence to research on coordination failure, leader identity, policy alternatives for promoting integration of minorities, and conflict.

We thank Debayan Pakrashi and the Indian Institute of Technology (Kanpur) for their hospitality and logistical support. Nidhila Adhusumalli, Kunal Dixit, Gunjita Gupta, Ashwin Nair and Aradhana Singh provided exceptional field supervision. We thank Jordi Brandts, Antonio Cabrales, Utteeyo Dasgupta, Saumitra Jha, Anandi Mani, Eva Ranehill, Farah Said, and seminar and conference participants at several universities for extremely useful comments. This study is registered in the AEA RCT Registry and the unique identifying number is “AEARCTR-0002353.”
1. Introduction

Coordinating economic actions across individuals can be critical to resolving collective action problems and market failure. For instance, coordination may be necessary for escaping poverty traps, changing social norms, optimizing resource use on common land, or raising the provision of public goods (Coleman, 1987; Kremer, 1993; Hoff, 2000; Hoff and Stiglitz, 2001; Bowles et al., forthcoming). Coordination may be particularly difficult to achieve in diverse societies with a history of intergroup conflict. In this paper, we examine how leader identity influences coordination in mixed-identity groups.

We experimentally vary the religious identity of the leader in a coordination game implemented in mixed-religion groups across 44 towns in India, a country of considerable religious and social diversity and a long history of intergroup conflict. We use a weakest link turnaround game (as in Brandts and Cooper, 2006), a key feature of which is that individual payoffs depend positively upon the minimum effort in their group and negatively on their own effort. Payoffs are designed such that coordination tends to occur at the lowest effort level, in an inefficient equilibrium. Leaders can induce coordination by proposing a (non-binding) effort level.

Alongside investigating the role of leader identity in a baseline environment with no intervention, we examine coordination outcomes by leader identity under two policy-relevant interventions. We randomize groups into two treatment arms, one implementing affirmative action, and the other an intergroup contact intervention. We then examine how leader identity influences leader effectiveness in these two “policy” regimes. These interventions are commonly used to improve representation and social integration of minorities and we provide the first evidence of how they compare when leader identity varies, in an experimental setting on matched samples. Further, since our treatment arms are stratified across areas of high and low recent religious conflict, we are able to examine whether the impact of leader identity and the specific policies differ across the two conflict environments, which no previous work has done.

Our study contributes to the literature on leader identity in several ways. First, in a departure from previous work that can only identify the combined impact of leader preferences (or actions) and citizen reactions, our experimental design allows us to isolate citizen reactions to leader identity, controlling for leader actions.\(^1\) Second, we are the first to study citizen coordination, an

\(^1\) The political economy literature has mainly focused on the identity of political leaders. Citizen-candidate models (Osborne and Slivinski, 1996; Besley and Coate, 1997) allow leader identity to affect policy outcomes, in contrast to
aggregate outcome, when leader identity varies. Previous work has tended to focus on the impact of leader identity on whether leaders reallocate public goods towards their own group (Pande, 2003; Burgess et al., 2015). Third, we examine how leader identity influences coordination across different policy environments and different histories of conflict. A laboratory style experiment in the field permits identification of the relative effectiveness of distinct mechanisms, absent the selection and endogeneity problems that might otherwise be present. Overall, this work pushes forward the frontier on the open question of what makes some leaders more effective than others (Brandts et al., 2007; Brandts et al., 2015; Weber et al., 2001).

Our work also makes several contributions to the experimental literature. While previous work has shown that introducing a leader, who proposes an effort level, can facilitate the transition to a more efficient outcome (Brandts et al., 2015), no study has examined whether leader identity matters for leader effectiveness in improving coordination, or how leaders’ effectiveness depends on the policy environment. Previous leader-coordination studies have almost entirely been conducted in the laboratory. We conducted our experiment in the field in India’s largest state, Uttar Pradesh, where religious identity is salient to politics and conflict. In the experiment, 1028 Hindu and Muslim subjects from 44 towns participate in groups of four. Over half the towns were selected from districts that had a history of inter-religious conflict. We introduce a leader after four rounds of the game, and we model changes in minimum effort at the group level as a function of leader identity.

We report four main findings. First, the introduction of Muslim leaders increases minimum group effort by 31%, thereby coordinating group outcomes to a Pareto-superior equilibrium, while the introduction of Hindu leaders has no significant impact on coordination. This result is robust to the inclusion of town fixed effects and to several specification checks. Investigating mechanisms, we find that this does not arise from Muslim leaders proposing higher effort, but rather from citizen reactions to leader identity. In particular, the results are consistent with stronger in-group behavior among the minority group (as in Bisin and Verdier, 2011; Gupta et al., 2018).

Downsian models where only the identity of the median voter matters. Empirical analysis of the role of leader identity in political settings include Pande, 2003; Chattopadhyay and Duflo, 2004; Chin and Prakash, 2011; Bhalotra et al., 2014; Meyersson, 2014; Burgess et al., 2015; Brollo and Troiano, 2016; and Bhavnani, 2017. Jones and Olken, 2005 investigate the role of leaders in improving GDP growth.

2 See Hogg, 2001 for a theoretical analysis and Devetag and Ortmann, 2007 for a survey of this literature.
3 See, among others, List and Reiley, 2002; Brandts and Cooper, 2006; Brandts and Cooper, 2007; Brandts et al., 2007; Brandts et al., 2015; Brandts et al., 2016; Cartwright et al., 2013. Almost all prior papers on coordination use lab settings; notable exceptions are Brooks et al., 2015 and Polania-Reyes, 2016.
Second, we find that intergroup contact (achieved by having mixed-identity groups collaborate in solving a puzzle before coordination is measured) improves coordination irrespective of leader identity. This has implications for policy, for example, motivating de-segregation. Previous work shows that segregation can act to intensify existing prejudices (Glaeser, 2005; Enos and Gidron, 2016; Field et al., 2008), and our results complement this work, showing that even a short exposure can improve coordination, consistent with lower prejudice. Intergroup contact is possibly the most common policy suggested to reduce intergroup conflict (Paluck et al., forthcoming), and previous work suggests it can change attitudes and improve cooperation towards the out-group (Dahl et al., 2017). However, no previous work has analyzed the effectiveness of contact in improving coordination, nor how this varies with leader identity (and conflict history).

Third, we find that the impacts of affirmative action (AA) depend critically upon leader identity. Introducing a quota for Muslim leaders leads to an increase in coordination in Hindu-led groups. However, it leads to a deterioration of coordination in Muslim-led groups, consistent with backlash against Muslims and an increased sense of solidarity among Hindus. The AA literature is dominated by the analysis of gender quotas, and it does not investigate coordination as an

---

4 Coordination is different from cooperation. Cooperation is usually measured by the willingness to contribute in a standard public goods game, in which payoffs depend on the sum of other players’ contributions and there is only one pure-strategy Nash equilibrium. Instead, in the “weakest link” coordination game where payoffs depend on the minimum of other people’s contributions, there are multiple pure-strategy Nash equilibria that can be Pareto-ranked. Conceptually, non-zero contributions in a public goods game can be related to altruism, trust or other prosocial motivations, and the leader’s role can be thought of as encouraging such motivations. In contrast, non-zero effort in the coordination game is individually rational and the leader’s role is mostly to guide the group towards a specific equilibrium i.e. to act as a focal point.

5 See, among others, Pettigrew and Tropp, 2006; Burns et al., 2015; Ashraf and Bandiera, 2017; Bertrand and Duflo, 2017. In their survey of about 500 studies on this topic, Pettigrew and Tropp, 2006 find that only 5 percent use randomized samples, making causal claims difficult. They also observe the scarcity of research using field samples (as opposed to student samples in a lab) or developing country samples, raising questions about the external validity of the findings on intergroup contact. Some recent studies use random assignment of groups to test contact in a developing country setting (Lowe, 2017; Rao, 2018; Scacco and Warren, 2018). Bhavnani et al., 2014 study the effects of intergroup contact on violence in Jerusalem but their data are observational rather than experimental. Barnhardt (2009) finds that contact between Hindus and Muslims in India reduces anti-Muslim prejudice.

6 Gender quotas are now implemented in over 120 countries (Quota Project, 2016). One strand of work studies how quotas influence policy outcomes, gender norms, women’s aspirations and political participation (see, among others, Chattopadhyay and Duflo, 2004; Adams and Ferreira, 2009; Beaman et al., 2009; Ahern and Dittmar, 2012; Beaman et al., 2012; Iyer et al., 2012; Matsa and Miller, 2013; Gangadharan et al., 2016). Experimental research on affirmative action almost exclusively focuses on whether gender quotas encourage women to take part in tournaments (Schotter and Weigelt, 1992; Balafoutas and Sutter, 2012; Niederle et al., 2013; Leibbrandt et al., forthcoming).
outcome. Importantly, ours is also the first study to analyze affirmative action and intergroup contact in the same experimental setting, allowing for a direct comparison of their impact.

Fourth, we re-estimated the impact of leader identity and the different policies, distinguishing towns in neighboring districts with a high vs low intensity of Hindu-Muslim conflict in the previous 30 years. We compare coordination under different treatments within each district, so that district-specific unobservables do not contaminate our findings. This novel design allows us to investigate how the efficacy of two policy interventions varies with a baseline measure of intergroup hostility. We find that conflict history does not significantly influence leader effectiveness in Hindu-led groups. However, intergroup contact increases Muslim leader effectiveness more in low conflict areas while AA decreases Muslim leader effectiveness primarily in high conflict areas. These results offer the first evidence of the relationship between conflict and coordination.

Overall, our findings are relevant to research in several areas that are currently distinct from one another, including coordination, leader identity, quotas, segregation, in-group bias and conflict. The rest of the paper is structured as follows. Section 2 provides contextual information on religion and politics in India. Section 3 describes the data collection, Section 4 delineates the experimental design and Section 5 discusses the regression specifications. Section 6 presents the empirical results and Section 7 concludes.

2. Context: Religion and Leadership in India

India is a secular country, with the constitution enshrining the fundamental right to freely “profess, practice and propagate religion.” India is also a religiously diverse country. Muslims are the largest religious minority in India, constituting 14.2% of the population or 172 million people according to the 2011 census. India has the third largest Muslim population in the world, next to Indonesia and Pakistan. Close to 40% of Muslims live in urban areas relative to 29% of Hindus. The standard of living of Muslims is generally lower than Hindus: 43% of Muslims are illiterate.

---

7 The closest paper to ours is Gangadharan et al., 2016, who examine citizen reactions to the gender (rather than the religion) of the leader in an experimental setting. We differ from this paper by focusing on coordination rather than cooperation outcomes, and by investigating two specific policies and conflict histories.

8 Previous work on post conflict policies is often either correlational, or conducted at the country or region level. The empirical and experimental literature on conflict primarily focuses on the origins of conflict (see Blattman and Miguel, 2010, for a review) and its impact on growth (Rodrick, 1999), human capital (Miguel and Roland, 2011), psychology (Bowles, 2008), trust, cooperation and reciprocity (Bauer et al., 2014; Bauer et al., 2016; Cassar et al., 2013; Gilligan et al., 2014; Cecchi et al., 2016; Grosjean, 2014) and political participation (Bellows and Miguel, 2009).
relative to 36% for Hindus, 33% of Muslims are employed relative to 41% for Hindus and 25% of Muslims fall below the poverty line compared to 22% for all Indian citizens (NITI Aayog, 2016).

Muslims in India are disadvantaged in many domains (The Economist, 2016), there is a significant degree of residential segregation (Field et al., 2008), and both Hindu and Muslim communities exhibit positive in-group bias in trust (Gupta et al., 2018). Violence between Hindu and Muslims has occurred frequently in India generating insecurity, displacement, segregation and loss of property and life (Varshney, 2002). Previous research indicates that violence tends to disproportionately impact Muslims (Mitra et al., 2014). For instance, between 1985 and 1987, in the ten states with significant Muslim populations, Muslims experienced 60% of all deaths related to religious riots, 45% of all injuries and 73% of property damage (Wilkinson, 2004, p 30).

Compared to their population share, Muslims are under-represented in political office: over the period 1980-2010, only 7.6% of state legislators were Muslims (Bhalotra et al., 2014). Muslims are under-represented compared to their population share in all states, with the exception of the Muslim-majority state of Jammu and Kashmir. The low political representation of Muslims would be inconsequential if Muslim and non-Muslim politicians made the same policy decisions, but the religious identity of politicians does matter for policy outcomes such as health, education and sex-selective abortions (see Bhalotra et al., 2014 and Bhalotra et al., 2018). There are no quotas for Muslims in central government positions. However, some quotas for Muslims have been implemented in civil service and educational institutions in five states (Government of India, 2014).

3. Site Selection and Subject Recruitment

3.1 Site Selection and Balance Across Treatment Arms

Based on data on the incidence of religious violence over 1980-2010 (Kaysser et al., 2015), we selected two pairs of neighboring districts in Uttar Pradesh, India’s most populous state. Each district pair was composed of one high conflict district and one low conflict district (see map in Appendix Figure A1). One pair was in the western part of the state (Aligarh and Budaun) while the other was in the central part of the state (Allahabad and Pratapgarh).

The experiment was conducted in 44 sites in July 2017 with 1028 subjects. Within each district, we selected sites based on the following criteria: (i) they were officially listed as towns in the
census of 2011,\(^9\) (ii) their population was below 50,000, (iii) they had a relatively high population share of Muslims, and (iv) selected towns were comparable in their demographics across high conflict and low conflict districts. The average town in our experimental sample has 40% Muslims in the population, compared to the overall state proportion of 19%.\(^10\) We focus on towns rather than villages, as Muslims are more likely to live in urban areas and, related to this, inter-religious conflict is far more common in towns (Varshney, 2002). This has the added benefit of comprising of a more educated populace, reducing issues surrounding the understanding of the experimental tasks.

The 44 town level sessions consisted of 24 participants each, with a few exceptions due to recruitment difficulties.\(^11\) This resulted in a sample of 1028 subjects and 257 groups. The 44 sites are randomly assigned to three different treatment arms: 14 sites are retained as control, and 15 each are assigned to the “Contact” treatment and to the “Affirmative Action” treatment, which are described below. The assignment is performed within each district (i.e. implicitly stratifying by high/low conflict status) and by further stratifying by Muslim population proportion and total population. We verify that census 2011 and respondent demographic characteristics are balanced across the different treatment arms (see Table 1, Panels A and B). The final distribution of sites and number of respondents is shown in Appendix Table A1.

3.2. Subject Recruitment and Group Formation

To recruit participants for the experiment, our research assistants visited both the Hindu and the Muslim sections of each town, and distributed flyers containing information about participant requirements (age and numeracy), remuneration, time and location of the experimental sessions. Flyers were also posted at prominent landmarks and distributed at shops, temples and mosques. Upon arrival, participants were screened for eligibility (over the age of 18 and could read numbers) and their names were recorded on a participant list that was not visible to other participants. Upon commencement of the experiment, an equal number of Hindus and Muslims were selected from

---

\(^9\) Towns in India are defined as (a) Statutory towns i.e. all places with a municipality, corporation, cantonment board or notified town area committee or (b) All other places which satisfied the following criteria: (i) A minimum population of 5,000; (ii) At least 75 per cent of the male main working population engaged in non-agricultural pursuits; and (iii) A density of population of at least 400 persons per sq. km.

\(^10\) According to census 2011 figures, Hindus and Muslims account for more than 99% of the population of Uttar Pradesh state; all other religions (Christians, Sikhs, Jains, Buddhists etc) account for less than 1%.

\(^11\) In 3 towns a session consisted of 20 participants and in 2 towns sessions consisted of 16 participants.
the list. Once seated, participants were given a number tag representing their identification number. Individuals were assembled in a room and seated on mats, with four participants on each mat.

Individuals were then assigned to four-member groups (each called a “firm”), comprised of two Hindus and two Muslims. Upon commencement of the weakest link coordination task participants were informed that firm members were people within the session; they were also told that the people sitting on their mat were not part of their firm, so that they did not attempt to observe the effort choices of their physical neighbors. Individuals did not know who the other three in their group were; neither were they informed about the religious composition of their group. Effort choices in the coordination task were made using pen and paper, and participants were provided folders so that their effort choices were not visible to other players. They were also instructed and monitored not to look at other players’ choices. Each session was run with 6 research assistants including one experimenter. The experimenter read out the instructions while the research assistants helped answer questions and checked responses to the control questions. (see picture in Appendix Figure A2).

4. Experimental Design

Each experimental session contained a pre-experiment survey and three tasks: a puzzle task, a weakest link coordination task (run across six rounds), and a social norms elicitation task. Out of the three tasks, one was chosen randomly for payment. The session concluded with a survey of attitudes and respondent characteristics. Subjects knew that the session had multiple stages but were not given instructions about any particular stage until reaching that stage. We explain each component below.

4.1. Pre-Experiment Survey

Prior to commencement of the incentivized tasks, subjects answered a brief survey about their personal characteristics including height, hair color, religion and eye color (see Appendix Table A2). The survey was designed to elicit the religion of the subject. An important feature of the

---

12 In India, it is relatively easy to identity Muslims from their names. After recording participant names, research assistants would implicitly allocate names to religion. Religion was then cross-checked once subjects completed the pre-experiment questionnaire. Subject ID numbers were never matched with participant names, and the list of participant names were destroyed at the end of the session.
survey was that possible responses for questions 1 (height), 2 (hair color) and 4 (eye color) were designed such that all responses were the same. The only question with a differing response was question 3 which elicited the religion of the subject.

4.2. Puzzle Task

After the pre-experiment survey, all subjects participated in a jigsaw puzzle task. Each subject was allocated a 12-piece jigsaw puzzle. Participants completed the task individually in the control and affirmative action treatment groups, and in pairs in the contact treatment group. Our objective was to suppress competitiveness and have cooperative intergroup contact, since the latter has been shown to reduce prejudice (Paluck et al., forthcoming; Lowe, 2017). The time given for the puzzle assembly was twelve minutes and almost all participants were able to complete the task successfully in this time (the average time taken to complete the puzzles in pilots was about 8 minutes). If this task was chosen for payment, subjects were paid ₹ 400 for assembling the puzzle.

4.3. Weakest Link Coordination Task

After the puzzle task, subjects were randomly allocated to groups of four individuals, which we label “firms.” Each firm was comprised of two Hindu and two Muslim “employees.” Participants were not informed of the religion (or any other characteristics) of their firm members. The task structure is closely related to the minimum effort corporate turnaround game designed by Brandts et al. (2006), which is based on the minimum effort or weakest link coordination game of Van Huyck et al. (1990). This weak link production function -- a characteristic of many real world situations -- is prone to being caught in an inefficient equilibrium.

The task is run across six periods. In each period employees decide how many hours (H) to devote to firm activities. Their choices vary between 0 and 20 in intervals of 5: \( H_i \in \{0, 5, 10, 15, 20\} \). Employees’ payoffs for each period are determined by equation (1) below, where \( i \) indexes individuals and \( j \) indexes groups. The payoff table is illustrated in Appendix Table A3, where the units are Indian rupees.\(^{13}\) Participants were shown the payoff table but not the payoff equation. Working is costly, each hour worked costing an employee ₹25. Thus, payoffs are

\(^{13}\) 1 US dollar is around 68 Indian rupees.
decreasing in the employee’s own hours of effort, but they are increasing in the minimum hours worked in the firm. Coordinating on any of the available effort levels is a Nash equilibrium.

\[ \pi_{ij} = 500 - 25H_{ij} + \left[ \min_j (H_{ij}) \times 40 \right] \]

Given the payoff equation, it is only worthwhile for profit maximizing employees to raise their effort level if this will increase the minimum effort of the firm. For a profit maximizing employee to increase their effort by 1 unit, for example, from 0 to 5 hours, they must believe there is an 85.5% probability that each of the other three employees increase their effort.\(^\text{14}\) Given this, previous work has found that play often evolves towards the payoff-dominated equilibrium in which all players choose the lowest possible effort level (Brandts et al., 2006).

The task is split into two stages. The first stage repeats the coordination game described above across four periods (rounds). Employees work in the same firm across all periods. At the end of each period subjects are informed of the firm’s minimum effort. Employees are never informed of individual firm members’ effort choices. The first stage is designed to induce coordination on an inefficient equilibrium with low levels of effort, which we label “coordination failure” (Brandts et al., 2015). The absence of feedback about individual effort levels makes it more difficult to escape coordination failure in the turnaround game (Brandts and Cooper, 2006).

The second stage introduces a leader, and runs for two further periods. The leader’s role within each firm is to suggest a non-binding number of hours to work. In our experimental setting, all leaders are appointed and participants cannot elect or change the leader. Leaders do not have the scope to communicate with their employees beyond proposing an effort level, similar to other papers in the “leading by example” literature (Güth et al., 2007, Gächter et al., 2012, Gangadharan et al., 2016). All firm employees are informed of the leader’s proposal, but not the actual effort choice of the leader. All employees are provided information about the characteristics of their firm leader taken from the pre-experiment survey, in the same layout as the survey. They are told that the survey responses are the characteristics of the leader. As described earlier, the only characteristic that varies across leaders is their religion. However, to avoid making the research

\(^{14}\) To derive this probability, solve for \( p \) where \( 500 = 375(1 - p^3) + 575(p^3) \)
question salient, which might induce socially desirable response bias, subjects are given all the
leader’s characteristics (height, eye color, hair color, religion), and not just the leader’s religion.

Half of the firms in each session are assigned Hindu leaders and half are assigned Muslim
leaders. Leader identity is randomly allocated, and the player in each group who will be the leader
is also randomly selected. Our estimates for the impact of introducing a leader are thus specific to
leader identity. It is important to remember that the religious composition of firms is the same
across all firms, regardless of the leader’s religion. Leader characteristics other than religion, in
particular, gender, age, and family income are balanced across Hindu and Muslim leaders, though
Muslim leaders are less likely to have gone to college and more likely to pray several times a day,
similar to the variation observed in the overall population. We verify that participant characteristics
with regard to demographics, education, income and religiosity are balanced across groups with
Hindu or Muslim leaders (Appendix Table A4).

After being informed of the leader’s effort proposal and leader characteristics at the start of the
fifth period, similar to the earlier periods, employees are informed of their group’s minimum effort
in the previous period. All employees including the leader must then decide how many hours to
work. The leader’s effort, just like the effort of other employees, is not visible to the group. The
coordination game is repeated for two periods with the same leader, but with a new effort proposal
by the leader in each period. If this task is selected for payment, players are paid their coordination
game payoffs from two randomly selected periods.

We have two additional treatment arms where the same weakest link game is played, but with
changes to the environment in which the leaders operate, designed to mimic commonly proposed
policy interventions. We describe these treatments below.

4.3.1. Affirmative Action (AA) Treatment

Affirmative action policies, such as quotas, are common in both government and business to
increase participation of disadvantaged or minority groups. To measure the impact of quotas on
behavioral reactions to leaders of different religions, we randomize a third of the groups within
each district into an AA treatment. The game is conducted exactly as in the control arm described
above, with one important exception. Upon the introduction of a leader at the beginning of period
5, subjects are told that “similar to many government positions, 50% of the leadership positions in
this game will be reserved. Reservation will be made based on some characteristic in the initial
survey.” Since the only variation in characteristics in the initial survey is the subject’s religion, this is an indirect method of communicating to subjects that the 50% quota will be defined on religion.

Along with information on the leader’s characteristics (height, eye color, hair color, religion), employees with a Muslim (Hindu) leader are then informed that their leader is in a reserved (unreserved) position. While participants are not explicitly told that the reservation is based on religion, about 70% of respondents in the post-experiment survey correctly identified that the reservation was done on the basis of religion, with the rest citing other leader characteristics or saying “don’t know.”15 It is important to reiterate that here, as in the control arm, all groups contain two Hindu and two Muslim participants, and half of all groups within a session are assigned to Muslim leaders. By comparing the control and the AA treatment arms (and thus effectively comparing a Muslim leader with a Muslim leader who is leading through a quota) we can observe the impact of publicly announced quotas on the ability of leaders to coordinate groups.

4.3.2. Contact Treatment

We also investigate the impact of a randomized intervention that increases intergroup contact on citizen responses to leaders of different religious identity. The key difference between this treatment and the control arm is the implementation of the puzzle task. Unlike in the control arm and AA treatment, where puzzles are assembled individually, subjects in the contact treatment assemble the jigsaw puzzle with a partner from the other religion. The puzzle partner is a person sitting on the same mat as the participant, and therefore not a member of the same firm (see picture in Appendix Figure A3). Our survey confirms that only 14% of participants incorrectly identified the religion of their puzzle partner. Subjects are encouraged to talk with their partner during the 12 minutes allowed for the puzzle. Importantly, subjects in the sample towns often live in separate Hindu and Muslim communes, which limits interaction between the two communities. By comparing the control arm and the contact treatment we can infer the impact of intergroup contact on the ability of leaders to coordinate groups. During subject recruitment, we noticed considerable residential segregation of Muslims and Hindus in some of our study sites, making the contact

15 Our estimates, which are intent to treat estimates, will therefore underestimate the impact of religion-based reservation. Sample size considerations precluded the inclusion of a treatment with Hindu leaders being reserved and, in practice, quotas are usually for population minority groups.
treatment pertinent. A potential concern is that interacting with anyone, not necessarily from a different religion, prior to the coordination game may affect coordination. We expect that any such effect is small in this setting since the puzzle game is not competitive and does not require a second player to complete. Importantly, as we shall see below, we can reject this concern because we see no differences in minimum effort in the contact vs the control arm before the leader is introduced.

4.4. Survey

After the coordination game, participants participated in a social norms elicitation task, which could also be selected for payment. We do not analyze this task in this paper. After the completion of the task, participants answered a short questionnaire about their views on politics and inter-religious violence, and about their demographic and economic profile.

4.5. Experimental Procedure

At the start of a task, instructions were read aloud by the experimenter to establish common knowledge. To determine whether subjects understood the instructions, each participant answered a set of control questions in private both before the first period and at the start of the fifth period (when the leader is introduced). The experimenter and research assistants cross-checked the answers and started the experiment once satisfied that subjects understood the task. Prior to reading the weakest link coordination task instructions, subjects were given the payoff table shown in Appendix Table A3.

To ensure the anonymity of the leader, in all sessions, the leader’s proposed effort was elicited after the control questions were answered, but before collecting the control question answer sheets i.e. it was not possible to identify a leader by seeing who was writing a suggested effort, since everyone was answering control questions.

At the end of the session, each subject was privately paid in cash for one of the tasks (excluding the pre-experiment survey). The average payoff was ₹ 610 including a ₹ 200 show up fee. This constitutes about 2.5 days’ wage for a semi-skilled laborer.

5. Empirical Strategy

Our main outcome variable is the minimum effort exerted in the group in each round. This is the key determinant of player payoffs and is the standard measure of coordination in the weakest
link literature (Brandts and Cooper, 2006). We test whether leaders improve coordination by estimating the following specification:

\[
(2) \quad MinGroupEffort_{kjt} = \alpha + \beta_{kjt} + X'_{kjt} \gamma + \epsilon_{kjt} ; \quad t=1,2,...,6
\]

where \(MinGroupEffort_{kjt}\) is the minimum effort exerted by group \(k\) in town \(j\) in period \(t\), and \(Leader_{kjt}\) is a dummy variable that takes value one for periods 5 and 6, when a leader is introduced. This regression therefore compares the group’s minimum effort in periods with a leader to periods without a leader. \(X_{kj}\) is a suite of control variables that includes town fixed effects, demographic controls (average age, education, gender mix and monthly household income of the group members) and a control for religiosity based on prayer frequency. Standard errors are clustered at the group level. We run specification (2) separately for Hindu and Muslim leaders to examine whether leader identity matters for coordination outcomes. Recall that half of all groups within each town are randomly assigned to have Muslim leaders.

We then examine whether leader effectiveness varies across different policy environments by comparing coordination outcomes for the same leader identity (Hindu or Muslim) across the different treatment groups as follows:

\[
(3) \quad MinGroupEffort_{kjt} = \alpha + \beta_{1kjt} + \beta_{2kjt} * AA_{j} + \beta_{3kjt} * Contact_{j} + X'_{kjt} \gamma + \epsilon_{kjt} ; \quad t=1,2,...,6
\]

In equation (3), \(AA_{j}\) is a dummy that equals one if town \(j\) was randomly assigned to the affirmative action treatment and \(Contact_{j}\) equals one if the town was randomly assigned to the contact treatment. We estimate equation (3) separately for Muslim and Hindu leaders. \(\beta_{1}\) then captures the impact of the leader on coordination in the control arm, \(\beta_{2}\) estimates the differential impact of the leader in an AA environment and \(\beta_{3}\) estimates the differential impact of the leader in an environment with pre-game contact between members of the different religions.

For both specifications (2) and (3), we run a robustness test in which we restrict the analysis to periods 5 and 6, and control for the group-specific minimum effort in period 4 and the leader’s proposals in periods 5 and 6. This enables us to test whether the impact of leader identity can be attributed to differences in the leader’s proposal, or to differences across groups in the coordination
outcome in previous rounds of the game. In this robustness check, since there is no variation in the Leader variable across periods within a town, we cannot include town fixed effects.

6. Leader Identity and Coordination Outcomes

6.1. Leader Identity and Coordination in the Control Group

Consistent with the corporate turnaround game literature we find that groups tend to coordinate on the low-effort equilibrium in the absence of a leader, which we call “coordination failure”. The average minimum group effort is less than three hours at the end of period 4 (Figure 1).

A priori, it is not clear what to expect when we introduce Hindu and Muslim leaders. Previous research has identified that leaders improve coordination (see Brandts et al., 2015), however, this literature fails to account for leader identity. In heterogeneous societies, citizens often prefer their own social group over outside group members even at a cost to themselves or society (Bisin and Verdier, 2001). Considering both the leadership and identity literature, it is not clear ex-ante whether introducing a leader will improve coordination or reduce coordination because of strong ingroup preferences.

Consistent with the hypothesis that leaders improve coordination we find that introducing Muslim leaders significantly improves minimum group effort in periods 5 and 6. In contrast, introducing Hindu leaders does not. The efficiency gain in Muslim-led groups is large: minimum group effort increases by 1.07 hours, compared to the average of 3.45 hours in the pre-leader periods 1 through 4 (Table 2, column 1). In contrast, the presence of Hindu leaders leads to a decline of 0.488 in minimum group effort, which is not statistically significantly different from zero (Table 2, column 2 and 4). The effect of leadership on minimum effort is lower than in Brandts et al., 2015 who find that a randomly selected leader increases minimum effort from 3.33 to 11.25.16

The estimates are robust to controlling for the demographic and religious characteristics of group members (columns 3 and 4). The difference in coordination gains between Muslim and Hindu leaders is statistically significant (column 5). This holds even when we restrict the sample

16 For comparison purposes the minimum effort in Brandts et al., 2015 is rescaled. The lower impact of leaders in our context could be due to differences in the context (developed country lab experiment vs developing country field setting) or because leaders in our experiment could only communicate a numerical proposal while those in Brandts et al., 2015 had the ability to send more detailed messages to participants.
to periods 5 and 6, and control for the leaders’ proposal and for minimum effort in period 4 (Table 2, column 6).

The results are robust to using town random effects instead of town fixed effects, using an ordered probit specification rather than OLS, and to controlling for town*mat fixed effects to ensure that participants are correctly responding to the effort choices of their firm members rather than the effort choices of those seated on the same mat (results available upon request).

6.2. Potential Mechanisms: Leader Preferences vs Citizen Reactions to Leader Identity

We investigated why Muslim leaders might induce greater coordination than Hindu leaders. As discussed in the Introduction, leaders can influence outcomes through their preferences, or through citizen reactions to them. In general, preferences are difficult to comprehensively measure, but in our lab-in-field setting, leader preferences are proxied by leaders’ effort proposals. We find that Muslim leaders propose 10.5 hours on average, compared to 9.4 hours for Hindu leaders (Appendix Table A5), but the difference is not statistically significant (Appendix Table A6, column 1). The distribution of proposals by leader identity in the control arm is shown in Appendix Figure A4, and a Kolmogorov-Smirnov test shows that the two distributions are not different (p value 0.452). In any case, as shown above, the difference in minimum group effort is robust to controlling for leader proposals (Table 2, column 6). We can therefore reject leader preferences as an explanation of the greater effectiveness of Muslim leaders.

As a result, we can conclude that our findings are driven by citizen reactions to leader identity. In the rest of this section, we examine three elements of citizen reactions: citizen perceptions of leader competence; citizen beliefs about the effort that members of their group (including the leader) will exert; and indicators of in-group bias in individual effort choices. We have survey measures of citizen perceptions and beliefs, and experimental measures of individual effort. We are also able to leverage the fact that, within our sample there is variation across towns in whether Muslims are a minority or a majority of the population.

One possibility is that citizens perceive Muslim leaders as more competent simply because they have achieved a leadership position despite being from a disadvantaged minority group. We examined the competence hypothesis in two ways. First, we examined responses to a question in our post experiment survey asking “Do you think Muslim leaders are less capable relative to Hindu leaders?” We find that 27% of Hindus and 10% of Muslims agree with this statement, revealing
that Muslims have more faith in Muslim leaders than Hindus. However, the response to Muslim leaders does not differ significantly with the fraction of the group that believes Muslim leaders are less competent (Appendix Table A7, columns 1 and 2). This undermines the competence explanation.\footnote{Willingness to raise effort in response to the leader’s proposal may depend on a subject’s belief that the leader will behave consistent with their proposal. We find that Muslim leaders are more likely to follow their own proposals. 79\% of Muslim leaders in the control group make effort choices that equal or exceed their own proposals, compared to 65\% of Hindu leaders, a difference that is statistically significant (p-value=0.004). This is interesting but it does not on its own explain why Muslim and Hindu individuals respond differently to Muslim leaders.} Second, we examined whether the response to Muslim leaders is different in towns that have experienced Muslim mayors; 17 out of 44 towns in our sample elected Muslim mayors in the most recent urban local council elections of 2012. We find that in towns with Muslim mayors, there is a lower minimum effort response to Muslim leaders (Appendix Table A7, columns 3 and 4). This also challenges the competence explanation.

A second potential driver of citizen reactions is that they depend on beliefs about how other group members will react to leader identity (since it is group minimum effort that drives individual payoffs). To probe beliefs our survey asked individuals to estimate the hours worked by their fellow employees. Using these data, we control for beliefs and find that this does not change the coefficients on leader effectiveness (see Appendix Table A7, columns 5 and 6). It is plausible that individuals react differently to their beliefs about the leader’s effort than they do to their beliefs about the effort of other members of the group. To assess this, we controlled for participants’ beliefs about the hours worked by their leader, but again the coefficients of interest did not change significantly (Appendix Table A7, columns 7 and 8). Notice that this specification also controls for the possibility that revealing the leader’s religious identity may have changed employees’ beliefs about the religious composition of the group even though nothing was explicitly stated about this, since the leader is one of the four in the group whose effort counts towards minimum effort. Overall, this suggests that beliefs about the behavior of others is not the main driver of our results.

A final possibility is that in heterogeneous groups, where in-group bias may exist, leader identity could impact individual effort by activating such biases. Previous research shows that minority groups are more prone to engage in in-group bias (Bisin and Verdier, 2011; Gupta et al, 2018). To investigate this, we examine individual effort decisions, hypothesizing that Muslims supply less effort in Hindu-led groups and more effort in Muslim led groups. We expect the same
pattern among Hindus, but with smaller responses if, as the majority group, they have weaker in-group bias. We estimate the following specification:

\[(4) \text{IndividualEffort}_{ikjt} = a + b\text{Leader}_{kjt} + X_{ikjt} \cdot g + w_{ikjt} ; \quad t = 1,2,\ldots,6 \text{ and}\]

where \(\text{IndividualEffort}_{ikjt}\) is the effort choice of individual \(i\) in group \(k\) (of town \(j\)) and period \(t\). As before, \(X_{ikjt}\) includes town fixed effects, demographic controls and religious controls, and standard errors are clustered at the group level. We should however emphasize that individuals’ effort choices depend on both their own reactions to the identity of the leader and their expectations of how other individuals in the group will react to the leader’s proposal and the leader’s identity. Thus, the regressions above are not strictly comparable to the group minimum effort regressions which isolate the role of leader identity.

We report specification (4) in Appendix Table A8 for each of four cases: Muslim vs Hindu employees under Muslim leaders vs Hindu leaders. We find that Muslim employees exhibit significantly higher effort choices in groups with a Muslim leader (compared to the earlier periods without any leader), but do not change their effort choices when confronted with a Hindu leader (Appendix Table A8, columns 1 and 2). Similarly, Hindu employees do not change their effort choices when faced with a leader of the other religion (column 3). However, in contrast to Muslims, Hindu employees significantly reduce their effort choices in groups with a leader from their own religion (column 4). Statistical tests confirm that the differences in individual effort are significantly different across the two types of leaders, for both Muslim and Hindu employees (p-values 0.088 and 0.001 respectively). We verify that these results are robust to excluding the leader’s effort choices from this analysis and focusing purely on employees (Appendix Table A8, columns 5-8).

On average, Muslims are a minority group in India. However, in our sample, the proportion of the population that is Muslim varies dramatically from 12% to 89% across the experiment sites, and in 16 out of 44 towns Muslims are a population majority. We leverage this variation to examine whether the results are different in Muslim-majority versus Muslim-minority towns. Consistent with in-group bias being stronger in minority groups, we find that minimum group effort under Muslim leaders increases by a statistically significant 1.7 hours in towns where Muslim are in a minority, but by a statistically insignificant 0.2 hours in towns where Muslims are in a majority.
(Appendix Table A7, column 9). Although the difference is not statistically significant, the magnitude of the difference is compelling. There is no similarly large difference for Hindu led groups (column 10).

To summarize, our investigations indicate that the ability of Muslim leaders to induce greater coordination towards Pareto-superior equilibria is associated with in-group preferences being enhanced when faced with a leader from the same religion, and such activation possibly being stronger when the individual is part of a social minority group in the local area.

6.3. Leader Impacts in Different Policy Environments

In this subsection we analyze the impact of leaders under two different policies that have been proposed to redress societal disadvantage and conflict: affirmative action (AA) and intergroup contact. As described earlier, Muslims in India tend to be economically and socially disadvantaged and incidents of inter-religious violence occur every year in India.

We know of no previous investigation of AA impacts on coordination, although this seems like a first order question when AA is used to address imbalances among conflictual groups. A previous literature suggests that an AA policy could have a number of implications for the effectiveness of Muslim leaders. As demonstrated in Ip et al., 2018 an AA policy may improve outcomes of the recipient group if group members believe the recipient of the quota is disadvantaged. In this case a quota may be perceived as an effective instrument to overcome disadvantage. In contrast Ip et al., 2018 also show that when people believe that the recipient of the quota is not suitable for a leadership role (because they are less skilled or people do not believe the recipient of the quota is disadvantaged), then a quota will lead to backlash against the recipient group. Based on this evidence it is unclear how AA will impact coordination in Muslim led groups. AA policies may also impact the outcomes of non-recipient Hindus. As shown in Gangadharan et al., 2016 AA may strengthen the social identity of non-recipient groups, increasing ingroup solidarity. This should translate into stronger Hindu ingroup behavior.

There is a large literature on in group bias which typically finds that contact reduces prejudice but less effectively for ethnic or racial prejudice.18 No previous study has examined the impact of intergroup contact on coordination. Notwithstanding the lack of research on contact and coordination, general contact theory suggests that intergroup contact can have varying impacts on

the effectiveness of Hindu and Muslim leaders. Contact between two different groups may breed suspicion, fear, resentment, disturbance, and at times open conflict (Baker, 1934, p. 120). Therefore, contact may increase animosity towards the outgroup and reduce the effectiveness of both Hindu and Muslim leaders. In contrast, intergroup contact may increase the effectiveness of Hindu and Muslim leaders by increasing “mutual understanding and regard” (Lett, 1945, p. 35). As such, ex-ante it is unclear how intergroup contact will impact Hindu and Muslim led groups.

We examine the impact of contact and AA on minimum group effort using equation (3). We find that introducing leaders on average results in somewhat higher coordination in the AA treatment and significantly higher coordination in the contact treatment arm than in the control arm (Table 3, column 1). The effect of contact on coordination is significantly larger than the effect of AA (p value 0.05). In addition, the impacts of the two interventions differ significantly by leader identity. Intergroup contact improves minimum group effort under both Muslim and Hindu leaders compared to the control group, consistent with the contact hypothesis, but the difference is larger for Hindu leaders. For Muslim leaders, intergroup contact increases group minimum effort to 2.07 hours, compared to the 1.07 hour improvement in the control group, and this difference is not statistically significant (column 2). Under Hindu leaders there is a small decline in group minimum effort in the control group but a large and statistically significant increase of 2.755 hours in the contact treatment group (column 3). Minimum group effort in the contact treatment is thus almost the same across Muslim and Hindu leaders (see Figure 2).

The AA treatment, on the other hand, significantly decreases the effectiveness of Muslim leaders. Minimum group effort increases by a small and insignificant 0.23 hours for Muslim leaders in the AA group, much smaller than the 1.07 hour improvement obtained in the control arm (Table 3, column 2). For Hindu leaders, we find a large and statistically significant improvement in minimum group effort in the AA treatment: Hindu leaders improve average minimum group effort by 1.90 hours, which is only a little bit smaller than the improvement achieved under intergroup contact (column 3). These results are consistent with the hypothesis of increased backlash towards AA recipients and greater in-group solidarity among non-recipients.

We verify that these differences do not arise because of differences in leader proposals across treatment arms. Muslim leaders do not make statistically different proposals from Hindu leaders across any of the treatment arms (Appendix Table A6, column 2). While we may worry that groups in different policy environments undergo different rates of learning or updating over the course of
the game, our results go in the same direction and even become more significant after we restrict to the last two periods and control for leader proposals and behavior in previous periods of the game such as the minimum effort in period 4 (Table 3, columns 4 and 5).

Similar to the analysis for the control group, we examine individual effort decisions using the following specification separately for Hindu and Muslim employees under Hindu and Muslim leaders:

\[
(5) \quad \text{IndividualEffort}_{ikt} = f_0 + f_1 \text{Leader}_{kjt} + f_2 \text{Leader}_{kjt} \times AA_j + f_3 \text{Leader}_{kjt} \times Contact_j + X_{ikj}'g + z_{kjt}
\]

We find that the main driver of the different results across treatment arms is the effort choice of Hindu individuals. Muslim employees significantly increase effort when a Muslim leader is introduced (as discussed earlier), and this does not vary across treatment arms (Appendix Table A9, column 1). Hindu employees do not increase their effort when a Muslim leader is introduced, and again this is not significantly different across treatment arms, and a similar pattern is observed for Muslim employees in Hindu-led groups (columns 2 and 3). However, Hindu employees chose lower effort levels in Hindu-led groups in the control treatment, but they choose significantly higher effort in both the AA treatment and in the contact treatment (column 4). Particularly for the AA treatment this is consistent with the AA literature (Gangadharan et al., 2016) which identifies stronger in-group behavior in the majority group as a result of the introduction of AA.

According to Ip et al. (2018), differences in the outcome of gender quotas may be a result of differences in the belief about the existence of a gender skill gap. To explicitly test whether perceptions of skill differences can explain differences in coordination under AA under Muslim and Hindu leaders we again use the question from our post experiment survey that asks whether Muslim leaders are less capable than Hindu leaders, but this time comparing answers across treatment arms. The minimum group and individual effort responses to Muslim or Hindu leaders under AA are not significantly different for groups in which more individuals assess Muslim leaders as less capable (p-value = 0.567 for Muslim leaders and 0.645 for Hindu leaders.) This suggests that the documented backlash against Muslim leaders under AA is generalized rather than dependent on perceived skill differences between Muslim and Hindu leaders. The results discussed

---

19 The gender of an individual’s puzzle partner may also be important. We re-estimate equation (4) for the contact group participants, interacting leader with female puzzle partner. We find that participants with female puzzle partners respond less to the introduction of a leader, but the difference is not statistically significant.
so far average across areas with different histories of Hindu-Muslim conflict. It seems plausible that past conflict influences in-group behavior and, thereby, citizen responses to leader identity. We examine this in the next section.

6.4. Does Conflict History Matter?

We examine whether coordination outcomes under the two types of leaders in the treatment arms vary with whether the district has a high or low exposure to conflict over the period 1980-2010. This is pertinent since both policies have the potential to correct for historical grievances. It is important to note that the aim of this exercise is not to compare outcomes in high and low conflict areas directly, since many other observable and unobservable characteristics may differ across high conflict and low conflict areas.\(^{20}\) Instead, we take advantage of the fact that we randomly allocated towns to different treatments within districts characterized by high vs low conflict and we compare behavior across these randomized treatments within each conflict setting. Thus, we do not aim to identify the causal impact of prior conflict, but rather the effectiveness of Muslim vs Hindu leaders in each of two groups of areas with different conflict histories.

What differences might we expect based on conflict history? If areas with a history of intergroup conflict are also areas where in-group favoritism and out-group discrimination are higher, then it is likely that the majority group will react more adversely to an AA policy. The impact of conflict on the effectiveness of intergroup contact is more ambiguous. On the one hand, conflict-affected areas may be precisely those where intergroup contact is most limited to begin with, and so the contact treatment may have a larger effect. On the other hand, a history of conflict may reduce the receptiveness of individuals of both groups to contact.

We find some significant differences in the effectiveness of the two interventions by the history of conflict in the district. Muslim leaders improve minimum group effort in the control and contact treatments only in low conflict areas (Table 4, column 1). One possible explanation could be the low conflict areas tend to have greater levels of trust and labor market complementarities compared to high conflict areas (Jha, 2013). In high conflict areas, Muslim leaders have no impact on

\(^{20}\) Most of the characteristics documented in Table 2 are similar across towns in high conflict and low conflict districts, with the exception that female labor force participation and wage work are more common in the high conflict towns, possibly reflecting the fact that inter-religious violence in India is concentrated in more urbanized areas (results available on request).
coordination in the control or contact arms, and an adverse effect on coordination in the AA arm (column 2).

The impact of Hindu leaders on coordination is less sensitive to the history of conflict in the district, with the exception that coordination improvements in the contact treatment arm are in fact higher in high conflict areas (Table 4, columns 3 and 4). Hindu leaders do not improve coordination in the control arm but they do significantly improve it under both the AA and the contact treatments relative to the control, in both high conflict and low conflict areas.

7. Conclusions

We conducted a lab-in-the-field coordination game in India with a view to identifying the factors that affect leaders’ ability to improve coordination. We find that minority (Muslim) leaders improve coordination, but majority (Hindu) leaders do not. We show that this cannot be explained by differences in leader proposals (preferences), but is the result of citizen reactions to leader identity. In particular, we suggest that the results may be explained by stronger preferences by the minority for their own group. Our results provide the first evidence that leader identity is important in citizen decisions to coordinate economic actions, over and above the effects of differences in leaders’ preferences.

We test the effectiveness of leaders under both affirmative action and intergroup contact policies. We find lower effectiveness of (minority) Muslim leaders and greater effectiveness of (majority) Hindu leaders under affirmative action. These results are consistent with affirmative action generating backlash against its recipients, and increasing in-group solidarity among non-recipients. We also find that policies that encourage intergroup contact improve the effectiveness of both Hindu and Muslim leaders.

Finally, we examine differences in our results according to whether the towns are in districts with a greater or lesser history of inter-religious conflict. We find that the positive effect of Muslim leaders on group coordination stems from low conflict areas, intergroup contact does not increase the effectiveness of Muslim leaders in high conflict areas and affirmative action policies actually worsen group coordination. The effectiveness of Hindu leaders, on the other hand, does not vary much across areas of high or low conflict.

Our findings contribute novel evidence to research on coordination failure and on leader identity by bridging the two domains of research. In addition to documenting the role of citizen
reactions to leader identity in heterogeneous communities, our work provides useful guidance to
the policy and contextual constraints on the role of leaders in resolving coordination problems.

Our results are likely to be of general interest, as many societies are diverse, and civil conflict is rife. Blattman and Miguel (2010) estimate that, between 1960 and 2006, 20% of nations experienced at least ten years of civil war. The literature on ethnic diversity and civil conflict has grown rapidly but no previous work has examined the role of leadership: if minority ethnic or religious groups had leadership representation proportional to their size, would overall coordination and efficiency improve? Does affirmative action that corrects for imbalance in representation work to improve coordination, and how does this vary with whether the local (group) leader is in place through a quota or not? Similarly, does increasing non-competitive contact between the two groups lead to better coordination outcomes and, again, does this depend upon leader identity? Finally, does a history of conflict jeopardize the effectiveness of these interventions, or to what extent is remediation easier where high levels of conflict have not yet emerged? We address all of these questions, and thus contribute also to research on social integration and civil conflict. Importantly, our results for leader identity apply, in principle, not only to political leadership but also to leadership positions in other domains, for instance, in the police forces or the judiciary.
